

\* Last time: Converted all regex constructors to NFAs.

Upshot: We can combine these building blocks to generate an NFA recognising the same language as any given regex!

Example:  $r = \overset{r_1}{(00)} \overset{r_2}{|1} \overset{r_3}{)0}$

}  $L(M) = L(r)$ .  
 (I drew squares for states because circles look like zeroes)

\* Today: DFAs vs NFAs

NFAs are clearly more powerful than DFAs.  
Are they strictly more powerful?

Q: Given an NFA M, how much/how closely can you simulate it using a DFA?

# \* Scratch Work

Zoom in on 1<sup>st</sup>  $\epsilon$ -arrow  
 How to remove it?  
 (without messing up calculation)

} another part of machine

We were able to delete some  $\epsilon$ -labels at the cost of adding extra transitions labelled by letters.

Proposition: Given any NFA  $M$  that possibly has  $\epsilon$ -labels, there always exists an equivalent NFA  $M'$  which has no  $\epsilon$ -labels.

(Equivalent means that  $L(M) = L(M')$ .)

Pf: Skipped, but essentially it is what we did in scratch work, but more systematically.

\* Simplifying NFAs : remove  $\epsilon$ -transitions.  
 (We just stated that we can do this.)

\* Now suppose we have an NFA that has no  $\epsilon$ -labels.

Not a DFA

Problem : We can have zero or more outgoing arrows labelled by a given letter.

Look at calculation tree

$w = 0101$

}<sub>0</sub>

}<sub>1</sub>

}<sub>0</sub>

}<sub>1</sub>

After each step of the calculation tree, we reach some subset of  $Q$ .

Let us construct a "power-set" automaton.

Original NFA had  $Q$  as the state set.

Draw a new machine whose states are all possible subsets of  $Q$ .

This is a DFA, which does the same thing as the previous NFA.

E.g.  $w = 0101$  (compare this machine w/ previous NFA)

\* Summary

Consider an NFA  $M$ , suppose it has no  $\epsilon$ -arrows.

We construct a new DFA  $M'$  as follows:

- State set of  $M'$  is  $\mathcal{P}(Q)$ , where  $Q$  = state set of  $M$ .
- Start state of  $M'$  is  $\{q_0\}$
- Accepting states of  $M'$  are all subsets of  $Q$  that contain at least one accepting state of  $Q$ .

- Transition function:

Given ~~Q~~  $X \subseteq Q$  and ~~a~~ a letter  $a \in \Sigma$

$$\delta(X, a) = \bigcup_{q \in X} \Delta(q, a)$$

(for  $M'$ )

↑  
transition fn of  $M$

Apply the letter  $a$  to every state  $q$  of  $M$  that lies in  $X$ , and combine the outputs by a union.
